A B S T R A C T

Introduction: Helmand province, whose capital is Lashkar-Gah, is one of the most volatile provinces affected by the conflict in Afghanistan. Doctors without Borders began to work in Boost Hospital in 2009.

Results: 5719 surgeries were performed on 4394 patients. 47% were emergency interventions and 75% were first interventions. 39.7% (n = 1721) of patients were female. In the Gynecoc-Obstetric (G) area, the average age was 31.3 years. 848 Cesarean operations (76%) were performed and 95% of these were urgent. Of these patients (n = 598) 64% were at ASA II. Spinal anesthesia (SA) was administered in 44.4% (n = 415) of patients, followed by general anesthesia without intubation (GA-) in 39.3% (n = 367). In 16% (n = 151), general anesthesia was administered with endotracheal intubation (GA+). Transoperative mortality was 0.8% (n = 7).

Conclusions: The Boost Hospital offers a surgical service of relevance in the south of Afghanistan. This hospital is supported by Doctors without Borders (MSF) and has helped to reduce the maternal mortality in that region through the provision of quality care in obstetric emergencies. By applying health standards, and medical teams and material, MSF has helped the Afghan population, particularly gestating mothers, to improve its health while achieving a transoperative mortality in Cesareans of <1%.

Reduciendo la Mortalidad Materna en zonas de conflicto: Experiencia quirúrgica-anestésica en el Hospital Boost, Afganistán

RESUMEN

Introducción: Helmand cuya capital es Lashkar-Gah es una de las provincias más volátiles entre las más afectadas por conflictos en Afganistán. Médicos sin Fronteras empezó a trabajar en el Hospital Boost en 2009.

Método: Revisión retrospectiva de procedimientos quirúrgicos en Médicos sin Fronteras-Centro Operacional de Bruselas del 11 de febrero de 2010 al 30 de septiembre de 2012.

Resultados: Se realizaron 5719 cirugías a 4334 pacientes, siendo de urgencia un 47% y primera intervención un 75%. 39.7% (n = 1721) de pacientes fueron de género femenino. En relación al área Gineco-obstétrica (G), la edad media fue de 31.3 años. Se realizaron 848 cesáreas (76%) de las cuales el 95% fueron urgentes. De estas pacientes (n = 598) el 64% era ASA II. En cuanto al tipo de anestesia, se administró Anestesia espinal (SA) en un 44.4% (n = 415), seguido de anestesia general sin intubación (GA−) en un 39.3% (n = 367), y en un 16% (n = 151) se administró anestesia general con intubación endotraqueal (GA+); con una mortalidad transoperatoria de 0.8% (n = 7).

Conclusiones: El Hospital Boost brinda un servicio quirúrgico de relevancia en el sur de Afganistán. Dicho hospital es apoyado por Médicos sin Fronteras (MSF), lo cual ha ayudado a reducir la mortalidad materna en esa región con la provisión de asistencia de calidad en emergencias obstétricas. Con la aplicación de estándares de salud, equipo, y material médico, MSF ha logrado que la población afgana, y particularmente las gestantes, mejore su salud, logrando una mortalidad transoperatoria de intervenciones por Cesáreas de < 1%.

several departments including maternity, pediatrics, internal medicine, surgery, and emergency care. By the end of 2011, the hospital admitted an average of 1500 patients per month. In addition, external consultations were also offered to which more than 6000 patients per month attend. Many of these travel from areas outside Lashkar-Gah.\textsuperscript{16,17} Due to the reigning insecurity, MSF could not carry out activities involving active referrals with institutional ambulances, something which is a pillar of health care provision. Instead, it had to restrict itself to simply receiving patients that arrived by their own means to the hospital.\textsuperscript{18}

This study intends to describe the surgical-anesthetic activity carried out at Boost Hospital located in the city of Lashkar-Gah in Helmando province, Afghanistan. During the period of study, these activities were supported by the NGO Doctors Without Borders (\textit{Médecins sans frontières} – MSF).

### Method

The Brussels Operational Center of Doctors Without Borders (MSF-BOC), one of the five operational centers worldwide, is responsible for collecting data from projects around the world. The data from all of the surgical procedures performed in the operating room are recorded using a standard form developed by MSF. This data is transcribed monthly into an electronic database. This data is then reviewed in the Brussels Operational Center.\textsuperscript{19}

Boost Hospital is a unit with 180 beds and is equipped with services of maternity, pediatrics, internal medicine, surgery, intensive care unit, emergency radiology, laboratory, and two operating rooms, 24 h per day. In the Boost Hospital operating rooms the following personnel is on call: head of the room, anesthetist nurse, 8 anesthetic technicians, and one expatriate anesthesiologist.\textsuperscript{13} Close to 30% of emergency cases come from outside Lashkar-Gah, sometimes from areas more than 150 km away. This suggests there is a lack of services in remote districts.\textsuperscript{3}

For this study, a review of the statistical database of Boost Hospital for the period from February 11, 2010 to September 30th, 2012 was carried out. Variables of age, gender, surgical indication, and type of anesthesia were included. The surgical indications were classified as trauma (violence, accident), non-traumatic pathology (infection, ischemia, tumor, hemorrhage), or obstetric (prenatal and postnatal). Surgical procedures classified as minor included those related to wounds, visceral surgery, orthopedic surgery, gynecological/obstetric surgery, and specialized surgery.\textsuperscript{20}

As a retrospective review, this study complies with the ethical criteria of exoneration of the MSF review board.

### Results

Of the surgical patients, the male group predominated with 2613 patients (60.3%). The average age was 27.7 years with a range of 1–95 years. The main age group was 20–40 years. Of these, 52% (n = 22,680) patients were classified as ASA II, and 38% (n = 1647) were ASA I. 47.2% (n = 2698) of patients required emergency surgery. 75% (n = 4334) of patients underwent surgery for the first time. Of these, the causes of the intervention were trauma (T) in 44.3% of cases (n = 2540), 38.5% (n = 2222) non-traumatic pathology (P), and 17% (n = 957) obstetric patients (O).

Of the 5719 surgical procedures that were performed, 31.4% (n = 1795) were visceral surgeries (exploratory laparotomy, hernioplasty, hemorrhoidectomy, etc.), 24.4% (n = 1398) were wound surgeries (W: debridements, fasciotomies, finger amputations, etc.), and 19.3% (n = 1122) were gyneco-obstetric surgeries (C: Cesarean sections, ectopic pregnancies, vesicovaginal fistula, hysterectomy and variants, curettage, postpartum complications and others). The average surgical time was 50 min.

In terms of the type of anesthesia, 57% (n = 3258) used general anesthesia without intubation (GA–), 10% (n = 560) used general anesthesia with endotracheal intubation (GA+), 21% (n = 1219) used spinal anesthesia (SA), and 12% used other types. The transoperative mortality was 0.3% (n = 15) and 0.9% (n = 50) of patients received a blood transfusion.

In the gyneco-obstetric area (G), the average age was 31.3 years, with a range of between 12 and 90 years. 848 Cesarean sections (76%) were performed. Of these, 95% were emergency C-sections (Table 1). The surgical indication was fetal or maternal. Postpartum complications were not observed. Of these patients (n = 598), 64% were ASA II. When it comes to the type of anesthesia, spinal anesthesia (SA) was administered in 44.4% (n = 415) of cases, followed by general anesthesia without intubation (GA–) in 39.3% (n = 367), and general anesthesia with endotracheal intubation (GA+) in 16% (n = 151) of cases. Transoperative mortality was 0.8% (n = 7) (Table 2).

### Conclusions

In Boost Hospital, the surgical area is primordial due to the quantity of procedures performed. No statistical references are available to carry out a comparative analysis.

This hospital is supported by the NGO Doctors Without Borders. With the application of rigorous standards of health and minimal requirements for surgical activities, including infrastructure, medical team, and medical material, as well as strict adherence to policies, directives, and institutional therapeutic protocols, this organization has contributed to improved health among the Afghan population by achieving a transitory mortality rate of 1%. At the same time, after having performed 848 Cesareans and 58 interventions due to complications in the postpartum period, Boost Hospital helped, in this period, to directly reduce maternal mortality in this region. The hospital continues to offer this support at the present time.
