Abstract

Objective: To establish if 23 cm length, tunneled catheters, are associated to better outcomes than 19 cm ones.

Patients, Materials and Methods: Patients with CKD G5D, which the only vascular access alternative was the femoral vein. In these patients, the performance of different lengths of catheters was compared.

Results: During 103 months (from February 2009 to September 2017), 30 femoral tunneled catheters were implanted in 19 patients; 15 each group, mean age was 56.3 years. Thirteen (68.4%) were men.

Catheters with similar design, but with different lengths, yield comparable results in patency, complications and cause of removal.

Conclusions: We suggest using femoral catheters with lengths from 25 to 55 cm (from the cuff to the tip) to obtain best results because such lengths are necessary to reach positions near the right atrium.

Key words: Catheters, renal dialysis, renal insufficiency, chronic.

Resumen

Objetivo: establecer si la implantación de catéteres femorales tunelizados de 23 cm genera mejores resultados que los de 19 cm

Pacientes, materiales y métodos: pacientes con enfermedad renal crónica estadio 5, en los que se agotaran todos los accesos vasculares, siendo la vena femoral su última alternativa. En ellos se compararon los resultados en cuanto a eficiencia y complicaciones de implantar catéteres con diferente longitud.

Resultados: durante 103 meses (de febrero del 2009 a septiembre del 2017), 30 catéteres femorales tunelizados fueron implantados en 19 pacientes; 15 en cada grupo, edad promedio de los pacientes 56,3 años, 13 (68,4%) hombres. Los dos catéteres con diseño semejante, pero diferente longitud dieron lugar a resultados parecidos en cuanto a tiempo de funcionamiento, complicaciones y motivo de retiro.

Conclusiones: sugerimos que los catéteres femorales tunelizados para hemodiálisis deben de tener longitudes entre 28 a 55 cm (del retenedor a la punta) para lograr una mayor eficiencia, longitud suficiente que permita alcanzar territorios cercanos a la aurícula derecha.

Palabras clave: catéteres, diálisis renal, insuficiencia renal crónica.

Introduction

Native arteriovenous fistulae are the best option for hemodialysis patients, the second one is the arteriovenous synthetic grafts^{1,2}. However, in our country, 70% of incident patients to hemodialysis start therapy with a non-programed procedure³. Furthermore, the main etiologies of CKD are diabetes and hypertension, diseases that are associated to poor quality vessels and with poorer results in the construction and performance of the native access. In the superior thorax, different routes are depicted to use bilumen catheters. Internal jugular vein is the most frequently used⁴, but innominate⁵, axillary^{6,7}, and superior cava vein⁸ are also other alternatives, with a last resort being implantation in the right atrium⁹. If the superior thorax vessels are exhausted the next alternatives for vascular access are in the lower hemithorax¹⁰. The femoral vein is a very good option, and is used often for transitory catheters, there are few papers related with long term results of this vascular access, and with significant number of patients in dialysis with long term, tunneled, catheters¹¹. The general concept is better outcomes and better flux can be obtained with catheters which tip are in vessels with bigger diameter, thus with longer times, better dialysis dose, and less infectious and thrombotic complications. For Internal jugular vein catheters, the KDIGO guidelines establish the right atrium as the right position, this placement is achieved with 15 to 20 cm catheters, for the femoral accesses the right position is the inferior cava vein, this is achieved with 19 to 24 cm catheters¹². In this paper, we describe our experience with a significant number of cases with two different lengths of tunneled catheters placed in the femoral vein, with different positioning of the tip, and we report the long term outcomes and complications.

Materials and methods

Nineteen CKD E5D patients, over eighteen years, were included, with 30 procedures of implantation, all of them needed a vascular access for chronic

hemodialysis, and in all of them, another possible vascular catheter or arterial-venous fistulae, was excluded, furthermore the patients declined to begin peritoneal dialysis.

Demographic variables were gender; age, previous time in hemodialysis, number of previous catheters, type (no tunneled vs. tunneled) and location.

All the patients signed informed consent for the procedures.

The implantation procedures were performed in the procedure room of dialysis facilities by two experienced nephrologists in central venous catheters (CVC) implantation. All the procedures were made with B mode ultrasonography guide to locate the femoral vein and subsequent puncture of them. The procedures were made with local anesthesia, blood pressure monitoring and pulse oximetry.

For commodity of both, right handed, nephrologists, the right femoral vein was preferred first. If the ultrasonographic evaluation showed a bigger diameter, or if the metallic guide wire didn't progress easily inside the right femoral vein, the left vein was used as second option.

The procedures were done under aseptic conditions and with local anesthesia in the skin a tissue over the territory of the vascular-nervous complex femoral. The femoral vein was punctured, guide wire was passed and left in the vessel lumen and the needle was removed. Then we applied local anesthesia in the supra-inguinal region, in a horizontal trajectory of 2 cm, and about 10 cm distant of the vein puncture site. Then we applied local anesthesia along the trajectory from de supra-inguinal region until venous puncture site. With a scalpel, an incision was made in the supra-inguinal area and a subcutaneous tunnel was made advancing a tunneler from the incision to the exit site of wire guide, the catheter was introduced in the tunnel joined to the tunneler. Over the guide wire the vein was dilated with 12 French and 14 French dilators, then a 16 French Valved Pull-Apart Sheath/Dilator

was advanced to the vein, the dilator was removed and the flexible catheter was advanced at time the sheath was removed. Patency was verified, the incisions were sutured and the catheter was fixed to the skin of the anterior wall of the abdomen (**figure 1,2**).

After the implantation, a plain of abdomen was obtained to confirm the tip positioning (**figure 1,2**)

Complications during the procedure and 48 hours after were recorded (arterial puncture, lacerations to the vessels, retroperitoneal bleeding, hematoma). Long term complications were also recorded: venous thrombosis, kinking, displacement, extrusion, exit site infection, catheter related sepsis or bacteremia, pulmonary embolism.

Also, the operational time and the removing cause: malfunctioning, catheter related sepsis, exit

site infection, peritoneal dialysis therapy change, renal transplantation, catheter functioning death.

The procedure was declared successful if the blood flow (Qb) was over 200 ml/min.

Patients were allocated in two groups: the first (G1) had 8 patients which catheter were implanted between February 2009 to February 2014, in these days we only had 19 cm (length from the cuff to the tip) catheters, the second group (G2) had 11 patients which catheters were implanted from march 2011 to September 2017, in this period we had similar catheters but with 23 cm length (from cuff to tip).

To evaluate if the differences between both groups were statistically significant, the distribution probe "F" with the respective "p" value (the value for "p" was significant if inferior to 0.05) were used.

Figure 1. 19 cm (from cuff to tip) length femoral catheter, the tip location is mainly in the iliac vein.

Figure 2. 23 cm (from cuff to tip) length femoral catheter, the tip location is in L4.

Results

During 103 months (from February 2009 to September 2017), 30 femoral tunneled catheters were implanted in 19 patients; 15 each group, mean age was 56.3 years. Thirteen (68.4%) were men.

The total number of previously implanted catheters was 63; 28 in G1 (mean 1.9/patient), and 35 in G2 (mean 2.4/patient).

Previous sites for G1 were: jugular 17, axillary 3, innominate 1, no tunneled femoral 7; for G2 there were jugular 23, axillary 3, innominate 0, no tunneled femoral 10.

The mean functioning time for G1 was 132 +/- 164 days, and 234 +/- 172 days, the time was superior for G2, but was not statistically significant between groups (**table 1**).

The retirement causes for G1 were: malfunctioning by cloths 8(53%), change of access (arteriovenous fistula) 2, Renal transplantation 1, change to peritoneal dialysis (PD) 1, catheter related sepsis 1 and death 2; for G2 were: malfunctioning by cloths 6(40%), change of access (arteriovenous fistula) 2, renal transplantation 0, change to PD 3, catheter related sepsis 0, death 2, active at cutting point 2. The percentage difference of retirement for malfunctioning was not statistically significant (40 Vs. 53%).

Regarding the complications, any group had major bleeding, both during insertion or retirement. The procedure of retirement was performed for the same nephrologists, with local anesthesia in minor procedures room.

The radiographic control showed the 19 cm catheters tip between S1 and L5 (approximately iliac vein bed), meanwhile the 23 cm tip catheters was located between L3 and L4, area of the inferior cava vein (**figures 1, 2**).

There were no differences for numbers of previous catheters, hemodialysis time and functioning time between both groups, the table 2 shows the 'F' Value, with the respective "p" value, all superior to cutting point (**table 2**).

Table 1. Descriptive results.

Variable	Group 1	Group 2	Total
Sex (M)	8	5	13
Sex (F)	0	6	6
Mean Age	57.8	54.8	56.3
No. Of previous vascular catheters	28	35	63
Minimum previous time on hemodialysis (months)	20	11	11
Maximum previous time on hemodialysis (months)	126	103	126
Minimum functioning time (days)	7	5	5
Maximum functioning time (days)	510	540	540

Table 2. Statistical significance.

Variable	Mean	Standard Deviation	F Value	p Value
No. Central 19 cm length previous catheters	1.86	1.24	0.95	0.3358
No. Central 23 cm length previous catheters	2.33	1.39		
Time in Hemodialysis length 19 cm	69.2	28.59	0.11	0.7381
Time in Hemodialysis length 23 cm	65.4	32.96		
Functioning time 19 cm length catheters	132	164.11	2.75	0.1070
Functioning time 19 cm length catheters	234	172.68		

In the statistical analysis, the standard deviation of "previous time on hemodialysis" was 28,59 months for G1 and 32.96 months for G2.

Discussion

Femoral veins tunneled catheters are a valuable option in patients with "classic" routes exhausted.

The international consensus establishes the catheters tip ideally located in big diameter vessels to obtain better Qb (12), which means longer catheters. However, the fluid physics is complex, the blood flux decreases with de catheter length and is better as the diameter increases. Furthermore,

the flux change to turbulent instead of laminar with the curvatures that are frequent in tunneled femoral catheters, with turbulent flux the velocity is low and the environment is prone to thrombosis¹³. For femoral catheters is recommended the tip was located in the inferior cava vein, or near to the right atrium, that requires too long catheters¹².

Often the catheter is located in inappropriate beds such as lumbar ascendant vein¹⁴, hemyazigos accessory vein¹⁵, is therefore important to verify the

location of the tip with a simple plain radiography of the abdomen, mainly if the functioning is inadequate.

The implantation is related with complications such as Phlegmasia Cerulea Dolens¹⁶, retroperitoneal hematoma^{15,17}, abdominal compartment syndrome¹⁸, and iliac a femoral veins stenosis¹⁹.

There are few papers related with long-term outcomes and with adequate number of tunneled catheters. Zaleski GX et al in their three-year experience with 41 catheters and with lengths from 40 to 60 cm found frequent interventions by diverse causes and an increased susceptibility to infection²⁰. Chow Km et al in 14 catheters report better long-term permeability, with reasonable survival, and a lesser number of infections²¹. Falk A in his three-year experience with 86 catheters found low permeability and a significant number of complications²². Maya et al found in 22 patients with tunneled femoral

catheters low long-term permeability vs. jugular catheters and higher risk of deep vein thrombosis, although equal risk of infections²³. Al-Hwiesh AK in 14 patients with low follow-up time concluded these catheters are a reliable alternative for patients without any other access²⁴.

In our study, we observe the 19 cm length tunneled femoral catheters (from cuff to tip) the tip is located at level of iliac vein, while the 23 cm ones has the tip located in the cava vein (**figure 3**). Based on these observations are expected better results with de 23 cm length catheters. However, the results obtained were not different for both kinds of devices.

We can conclude that with longer femoral catheters (for example 28 to 55 cm, from cuff to tip), is likely the tip reaches major diameter venous beds, which allows better Qb, lesser possibility of thrombosis and better dose of dialysis.

Figure 3. Femoral catheter tip location related to vertebral bodies.
